Natural solution to beach renourishment

The Sandsaver is the new natural alternative solution to Beach Renourishment. The module works in two ways; First by breaking down the energy of the wave thus reducing erosion. Second, by allowing the wave, which contains sand, to pass through the tapered holes and onto the beach surface. When the water retreats, it has to pass through the small portion of the module allowing the sand time to settle onto the beach and not back into the surf, thus building beach.

- Promotes beach accretion, while preventing beach erosion
- Rotationally molded from polyethylene
- Modular design for simple installation, no chains or tethering system needed
- Inexpensive in comparison to alternative beach restoration methods
- Environmentally friendly, will not deteriorate

The Sandsaver is an improved design based on proven past technology successfully used at multiple locations including Hawaii, New Jersey and Michigan. Pictured to the right is the installation at Wheatley National Park in Michigan (Day 1).
